Introduction

Low physical functioning of patients with mitochondrial disease (MD) may be due to a diminished muscle mass. Improving body composition through a nutritional intervention might be a promising strategy. The aim of this study was to analyze body composition, nutritional intake and physical function and their interrelations in MD patients.

Methods – Nutritional Assessment

Food intake

- Dietary assessment
 - Protein intake (g/day)
 - Energy intake (kcal/day)

Body composition

- DXA measurement:
 - Fat free mass index (FFMI)
 - Fat percentage

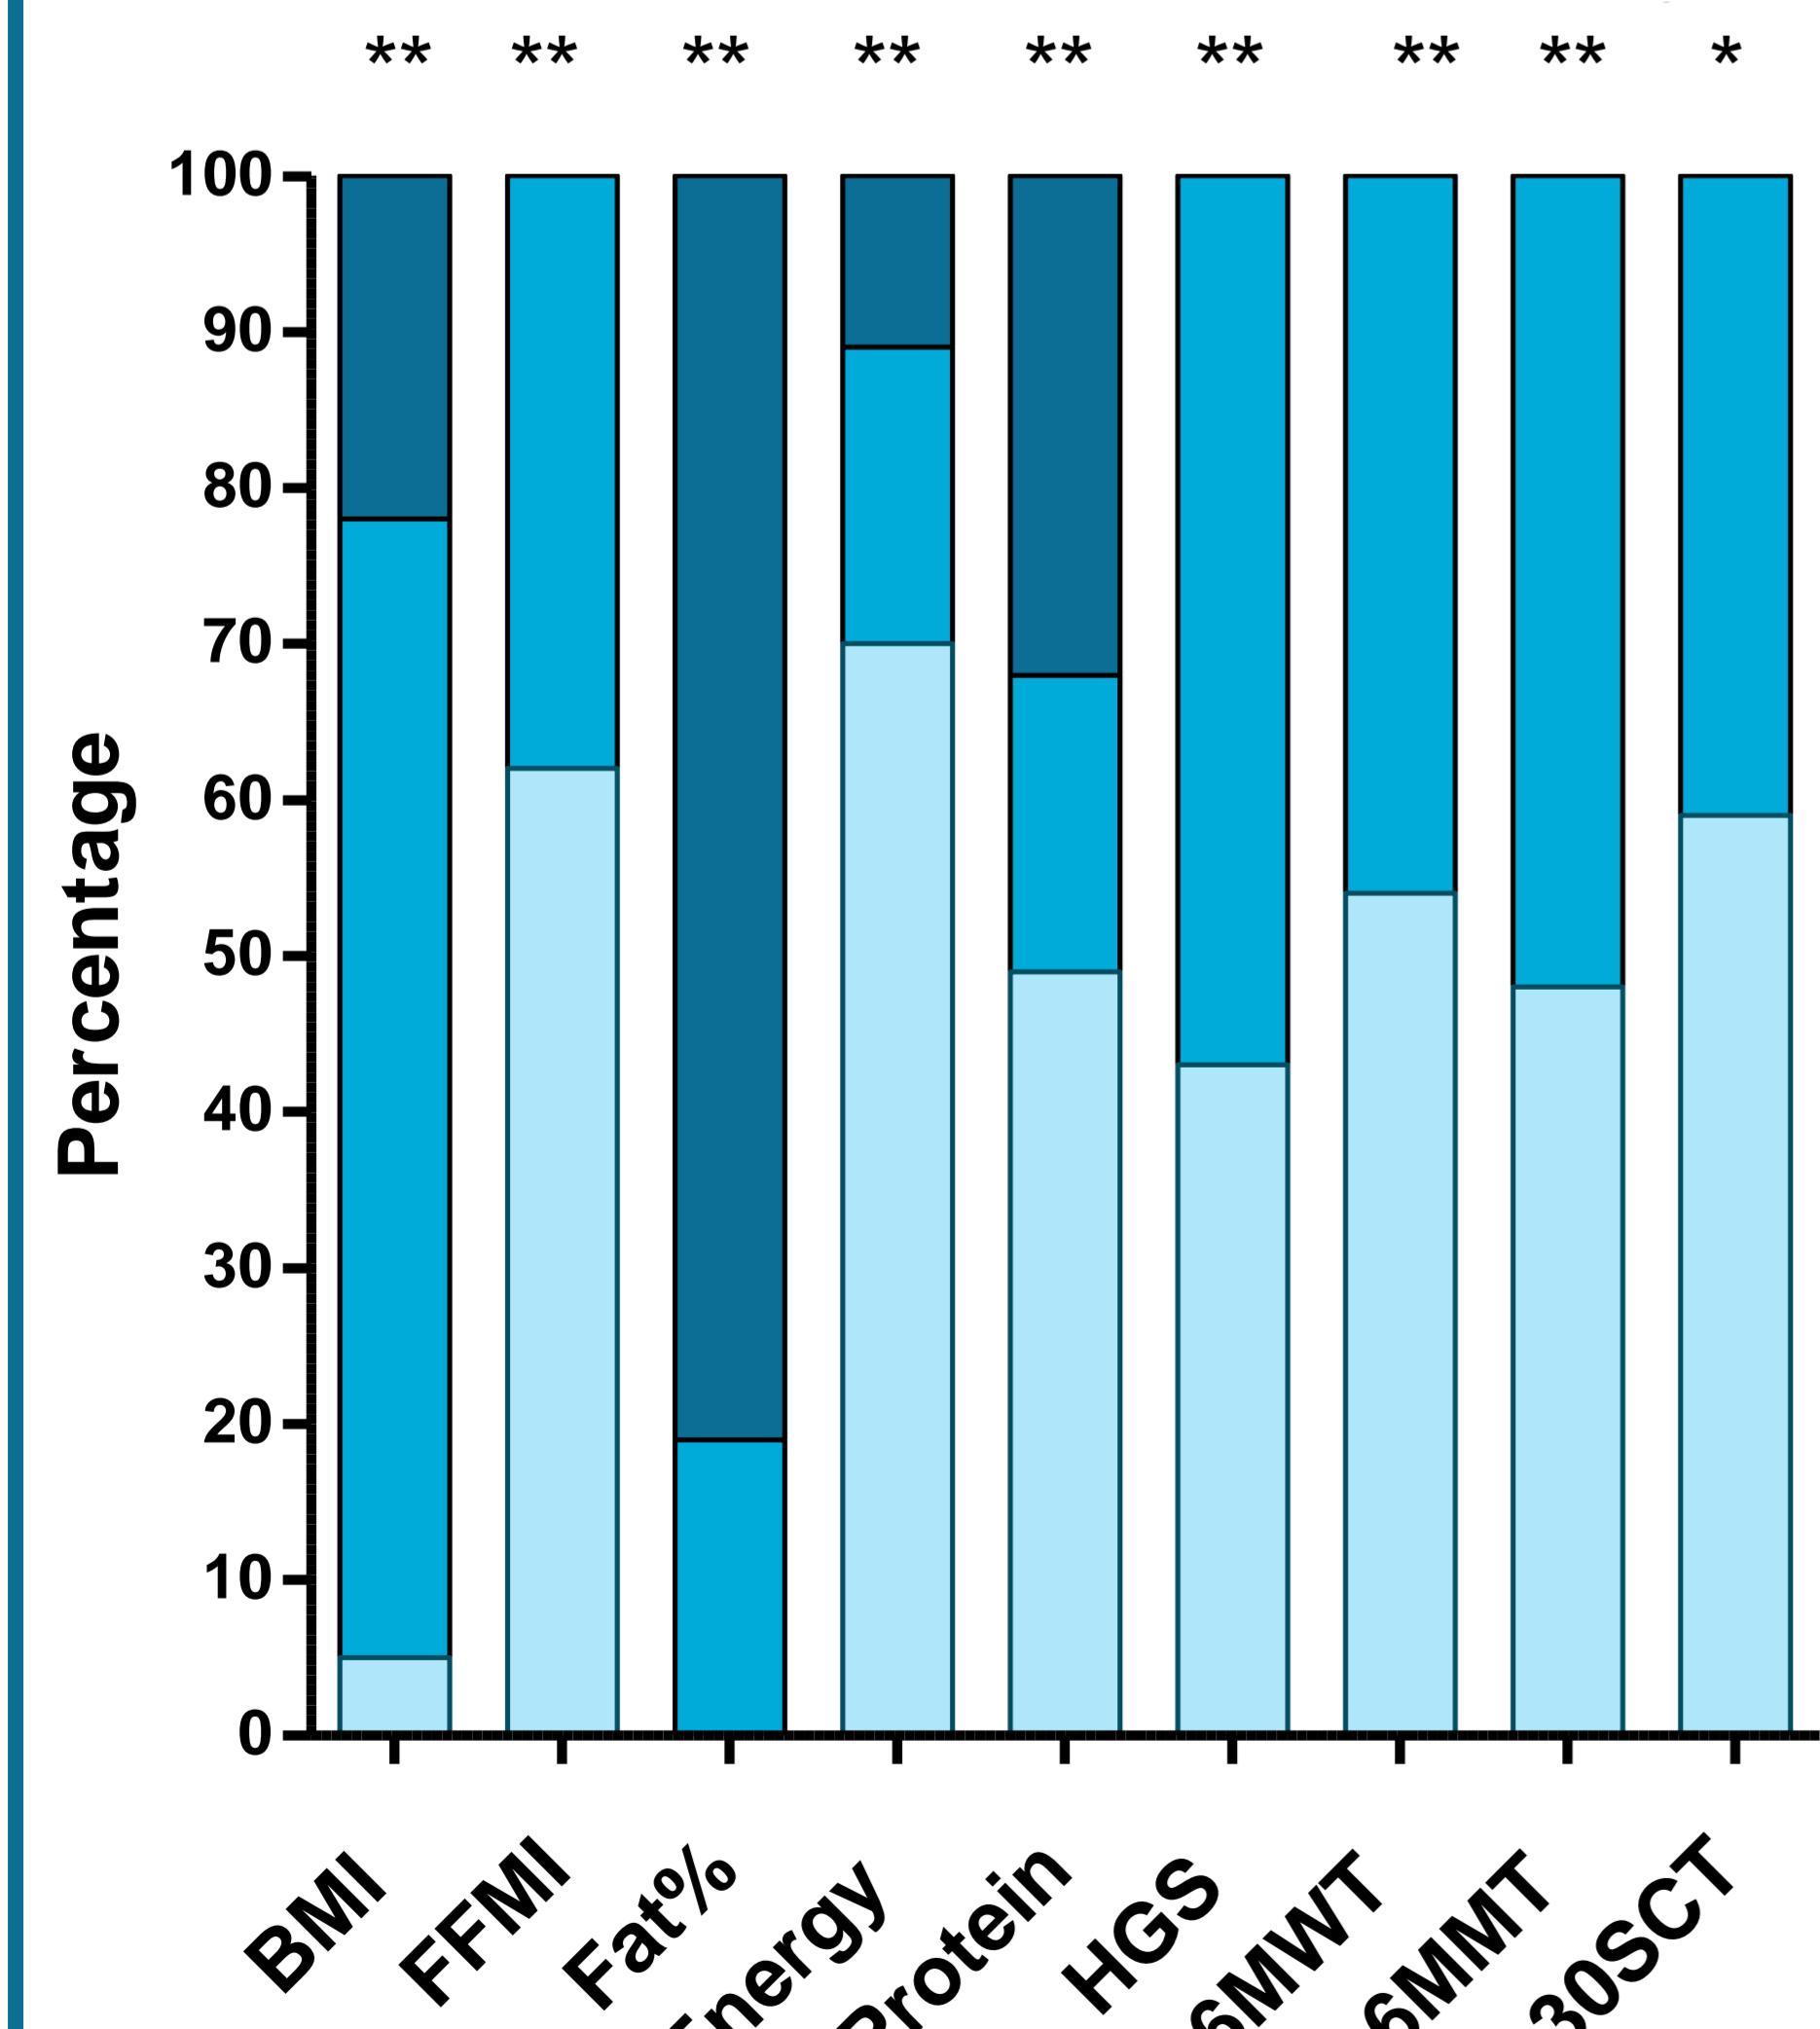

Physical performance

- Function tests
 - Hand grip strength (HGS)
 - 6 min mastication (6MMT)
 - 30 sec sit-to-stand (30SCT)
 - 6 min walking (6MWT)

Results

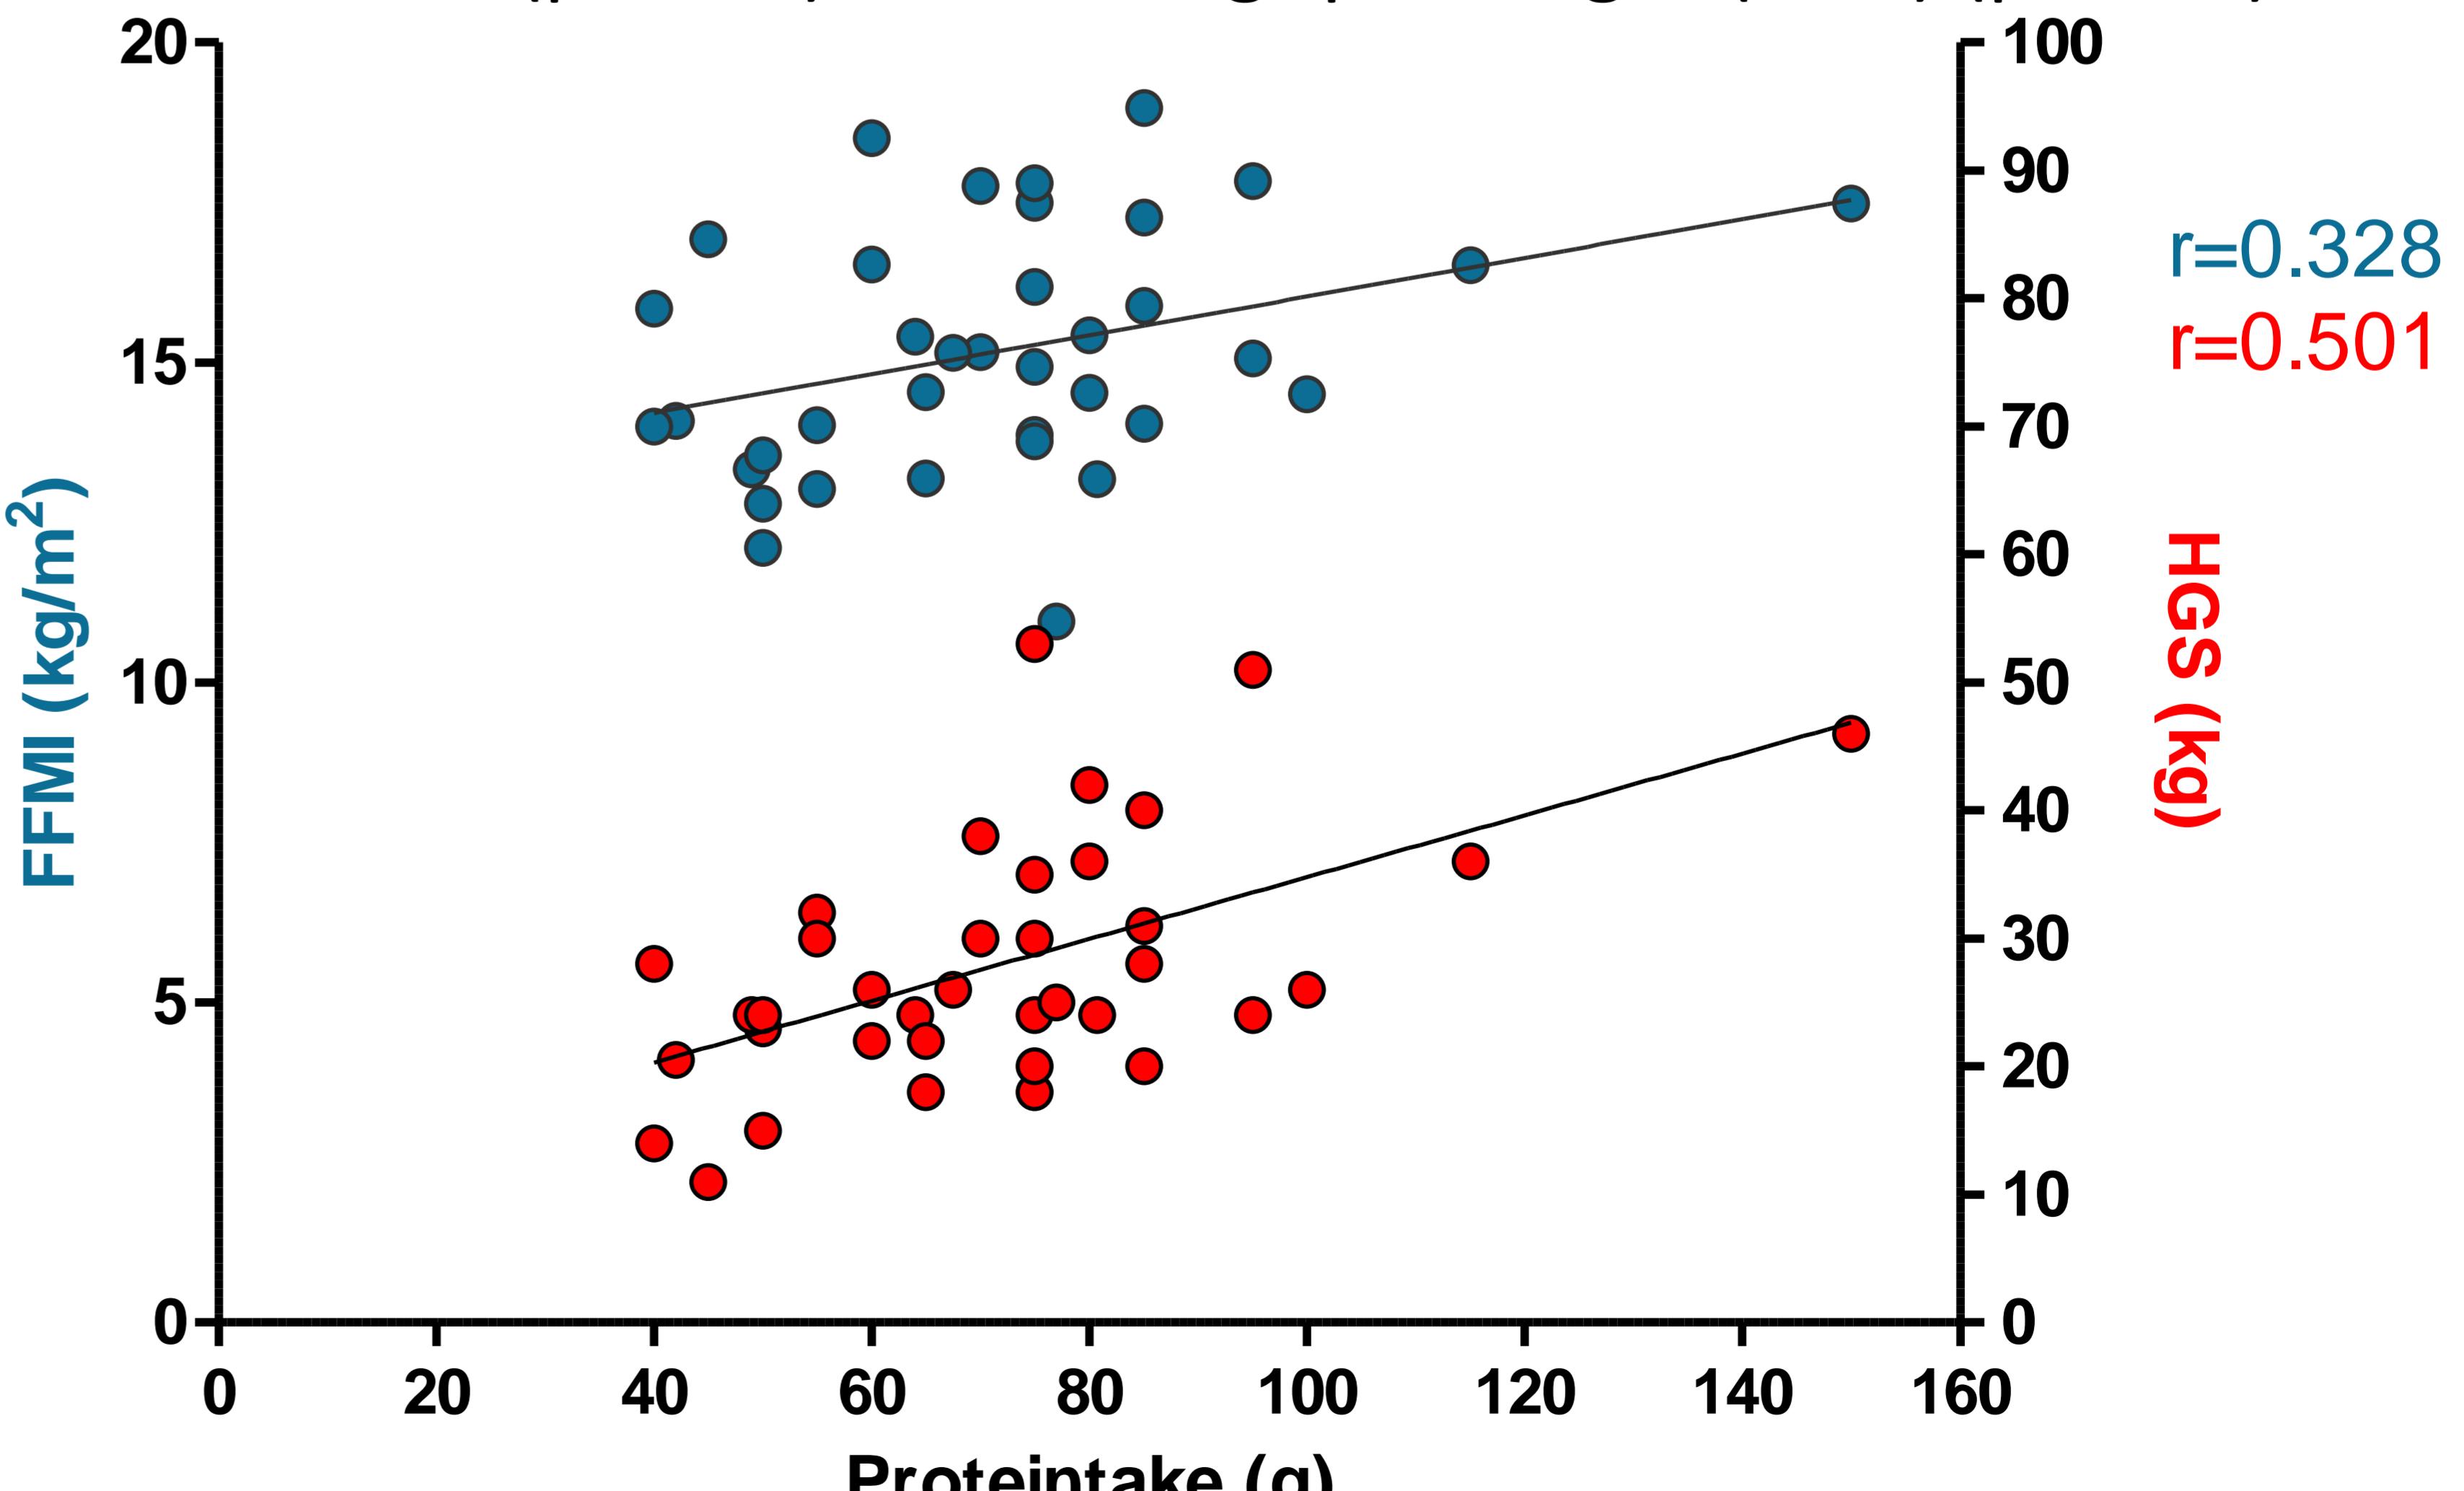

37 genetically proven MD patients (42 years \pm 13, 40% men, 78% m.3243A>G mutation).

Patients characteristics compared to references.

Legend:
too low (light blue)
normal (medium blue)
too high (dark blue)
T-test:
* p < 0.05
** p < 0.001

Significant correlations between protein intake and FFMI ($p < 0.05$) and hand grip strength (HGS) ($p < 0.01$).

Correlations between protein intake and FFMI and HGS
